A camera cannot detect its own lean. Only its neighbours can.
Which filters noticed the cameras that lean?
a flat row at 1.0 means the filter never suspected anything
health this camera was given
1.0 = "nothing wrong here"
lean 7 mm
lean 12 mm
lean 77 mm
lean 33 mm
camera A
camera B
camera C
camera D
Not just the typical case — the whole spread
honest = curve crosses 95 % left of the dashed line
fraction of updates at or below that value
(actual error)² ÷ (uncertainty the filter claims), log scale
A0 trust every camera equally (what is normally done)
A1 + reject sightings that disagree wildly (classical robust filtering)
A2 + measure how noisy each camera really is
A3 + judge each camera against a position built WITHOUT it
A4 + a floor on each camera's uncertainty that repeated looks cannot shrink (full method)
X1 the floor alone, without judging cameras against each other
X2 one shared floor for all four cameras instead of one each
edge of the claimed 95 % ellipse
