

Camera A — deployed-corrected residual

(b) does geometry predict the local SPREAD?
N = 125 detections · M = 5 cells (0.5 m, ≥ 5 each)
conditional: R^2 vs identity = -78.62 · cell Spearman = +0.70 · median obs/pred = 0.18
median per-cell BIAS removed first = 80 mm
ONLY 5 CELLS — too few to establish a trend; read as a scale check, not a fit

Point area in (b) scales with detections in the cell. σ_{pix} is fitted on leave-region-out folds, so each cell's prediction is out-of-region. Ground truth positions the dots in (a) and measures the residual; it never enters a projection, Jacobian or covariance. **READ THE LIMIT BEFORE THE RESULT:** only 3.1 x 6.9 m is sampled and image column tracks range at $|\text{rho}| = 0.91$, so range, image row and projection conditioning are collinear here. A weak or negative R^2 does NOT show that geometry fails -- it shows this dataset cannot test it.
