

Held-out variance-model comparison — after the deployed correction

(a) absolute held-out score, not a difference

(b) calibration: claimed RMS vs measured, % = held-out 90 % coverage
a model can buy coverage by claiming a huge sigma -- read both bars

All four models are fitted on leave-region-out folds and scored on the held-out fold. R1-iso, R1-range and R2-geom each carry ONE free parameter and differ only in the per-sample shape; R1-full carries three. Nominal coverage is 90 %. Ground truth scores the outcome and never enters a fit.
