

ACT 1 — the whole loop: predict, update, repeat (smoke1_20260716)

From a standing start: the cameras pull the belief in

PREDICT (up)
UPDATE (down)

When coverage lapses: the belief inflates until a camera sees it again

while a camera is watching, each drive step is worth tenths of a mm. 5.2 s without a detection and the belief inflates 1.8x — then the network pulls it back in.

Which camera the belief is listening to — coverage is a relay, not a chorus
