

Letting each camera rate its own noise: it separates them, and still does not help

smoke1_20260716, 539 detections, RETIRED v2 projection — mechanism evidence, not current camera accuracy. Under the current path all four cameras sit within 64.6–68.1 mm, so this is not a camera ranking (docs/localization_metrics.md).

Each camera now rates its own noise
and they do separate, in the order of this capture's residuals

But the SIZES come out far too small
a 77 mm bias is owned up to as 24 — short by 3.2×

And knowing the order does not help
both ways of learning end up worse than not learning at all
